## Nonconvex smooth opt guarantees

Consider solving  $\min_{x \in \mathbb{R}^d} f(x)$  with L-Lipschitz gradient via

$$x_{k+1} \leftarrow x_k - \alpha_k \nabla f(x_k)$$

with  $x_0 \in \mathbb{R}^d$ .

**Theorem** Suppose  $f$  is diff with L-Lips grad.

Then for  $T \geq 0$

$$\frac{1}{T} \sum_{k=0}^{T-1} \|\nabla f(x_k)\|_2^2 \leq \frac{2L (f(x_0) - \min f)}{T}$$

when  $\alpha_k = 1/L$  or with exact linesearch.

Moreover,

$$\frac{1}{T} \sum_{k=0}^{T-1} \|\nabla f(x_k)\|_2^2 \leq \max\left\{\frac{1}{\eta\alpha}, \frac{L}{2\tau\eta(1-\eta)}\right\} \frac{(f(x_0) - \min)}{T}$$

when we use Armijo backtracking. +

Consequence

Picking  $T = \Omega\left(\frac{1}{\epsilon}\right)$  then  $T \geq c \frac{1}{\epsilon}$  for  $c > 0$ .

$$\exists k \leq T \text{ s.t. } \|\nabla f(x_k)\|_2^2 \leq \epsilon.$$

Warnings

- $x_k$  might not converge! Consider  $f(x) = \exp(-x^2)$

- Even if  $x_k \rightarrow x^*$ , the limit might not be a local min.

Exercise: Think of an example where this happens.

Proof: We prove it for  $\alpha_k = \frac{1}{L}$ , the rest of the proofs are similar.

By DL, we have  $\forall k \geq 0$

$$f(x_{k+1}) \leq f(x_k)$$

$$- \frac{1}{2L} \|\nabla f(x_k)\|^2$$

Summing all of these up to  $T-1$

$$f(T) \leq f(x_0) - \frac{1}{2L} \sum_{k=0}^{T-1} \|\nabla f(x_k)\|^2$$

$$\Rightarrow \sum_{k=0}^{T-1} \|\nabla f(x_k)\|^2 \leq 2L [f(x_0) - f(x_T)] \\ \leq 2L [f(x_0) - \min f].$$

Dividing both sides by  $T$  gives the result.  $\square$

The reason why we have such slow converges is that our function can grow very slowly

$x^{100}$

When the gradient is small, you don't move that much.

Theorem. Assume  $f$  is twice diff and  $x^*$  is a second-order critical point  
 $\nabla f(x^*) = 0$  and  $\nabla^2 f(x^*) \geq \lambda I$

$$\lambda_{\min}(\nabla^2 f(x^*)) \geq \lambda$$

Assume that  $\|x_{k+1} - x^*\| \leq \|x_k - x^*\|$ .

Then, if  $x_0$  is close enough to  $x^*$ ,

$$f(x_{k+1}) - f(x^*) \leq \left(1 - \frac{\lambda^2}{4L^2}\right) (f(x_k) - f(x^*)) \quad \forall k \geq 0.$$

↑ why is this  $\leq 1$ ? →

Intuition

For points where 2<sup>nd</sup>-order approximation grows, we have

that if we start close

$$\Rightarrow T = \Omega\left(\left(\frac{\lambda^2}{L^2}\right)^{-1} \log\left(\frac{f(x_0) - f(x^*)}{\epsilon}\right)\right)$$

suffice for  $f(x_*) - f(x_0) \leq \varepsilon$ .

Proof: Since  $\lambda_{\min}(\nabla^2 f(x))$  is continuous  $\Rightarrow \exists \varepsilon > 0$  s.t.  $\forall x \in B_\varepsilon(x^*)$

$$\lambda_{\min}(\nabla^2 f(x)) \geq \frac{\lambda}{2}.$$

Then, for any  $\|\bar{s}\| \leq \varepsilon$  we can define

$$\varphi_s(t) = f(x^* + t\bar{s}) \quad \text{and}$$

$$\varphi'(1) = \varphi'(0) + \int_0^1 \varphi''(t) dt$$

$$\begin{aligned} \Rightarrow \nabla f(x^* + \bar{s})^\top \bar{s} &= 0 + \int_0^1 \underbrace{s^\top \nabla^2 f(x^* + t\bar{s}) s}_{\geq \frac{\lambda}{2} \|\bar{s}\|^2} dt \\ &\geq \frac{\lambda}{2} \|\bar{s}\|^2. \end{aligned}$$

$$\Rightarrow \frac{\lambda}{2} \|\bar{s}\| \leq \|\nabla f(x + \bar{s})\|. \quad (\because)$$

By Taylor Approximation:

$$\begin{aligned} \frac{L}{2} \|s\|^2 &\geq f(x^*+s) - (f(x^*) + 0^T s) \\ &= f(x^*+s) - f(x^*) \end{aligned} \quad (\heartsuit)$$

Combining  $(\heartsuit)$  and  $(\heartsuit)$  (★)

$$\frac{4}{\lambda^2} \|\nabla f(x+s)\|^2 \geq \frac{2}{L} (f(x^*+s) - f(x^*))$$

Then, using DL, and the fact that  $x_k \in B_{\frac{1}{2}}(x^*)$

$$f(x_{k+1}) - f(x^*) \leq f(x_k) - f(x^*)$$

$$\begin{aligned} &\quad - \frac{1}{2L} \|\nabla f(x_k)\|^2 \\ \text{Follows from (★)} &\quad \leq \left(1 - \frac{\lambda^2}{4L^2}\right) (f(x_k) - f(x^*)) \end{aligned}$$

□

Better guarantees for convex functions

Lemma (Characterization L-smoothness for convex functions)

Suppose that  $f: \mathbb{R}^d \rightarrow \mathbb{R}$  is diff and convex.

Then the following are equivalent

1)  $f$  has  $L$ -Lipschitz gradient

2)  $\frac{L}{2} \|\cdot\|_2^2 - f(\cdot)$  is convex.

3)  $f(y) \leq f(x) + \langle \nabla f(x), y-x \rangle + \frac{L}{2} \|x-y\|^2$   
 $\forall x, y$

4)  $\langle \nabla f(y) - \nabla f(x), y-x \rangle \geq \frac{1}{L} \|\nabla f(y) - \nabla f(x)\|^2$   
 $\forall x, y.$

If further  $f$  is twice diff the following are also equivalent to the above

5)  $\nabla^2 f(x) \leq LI \quad \forall x$  ( $LI - \nabla^2 f(x) \succeq 0$ )

Intuition

$$f(x) + \langle \nabla f(x), y-x \rangle + \frac{L}{2} \|x-y\|^2$$

3)

Proof: (2)  $\Leftrightarrow$  (5)  $h(x) = \frac{L}{2} \|x\|^2 - f(x)$   
is convex

$$\Leftrightarrow \nabla^2 h(x) \succeq 0$$

$$\Leftrightarrow LI \succeq \nabla^2 f(x)$$

second order characterization

(2)  $\Leftrightarrow$  (3)  $h(x) = \frac{L}{2} \|x\|^2 - f(x)$  is convex

$$\Leftrightarrow h(x) + \langle \nabla h(x), y-x \rangle \leq h(y) \quad \forall y, x$$

$$\Leftrightarrow \frac{L}{2} \|x\|^2 - f(x) + L \langle x, y-x \rangle - \langle \nabla f(x), y-x \rangle \\ \leq \frac{L}{2} \|y\|^2 - f(y)$$

$$\Leftrightarrow f(y) \leq f(x) + \langle \nabla f(x), y-x \rangle + \frac{L}{2} \|x-y\|^2$$
